

Lab 3 732A97

Raymond Sseguya

2019-12-08

Data

```
library(dplyr); library(knitr)

trackrcs <- read.table("T1-9.dat",
  col.names = c("countries", "x100m", "x200m",
    "x400m", "x800m", "x1500m", "x3000m", "marathon"))
rownames(trackrcs) <- trackrcs[,1]
```

Question 1: Principal components, including interpretation of them

a) Obtain the sample correlation matrix R for these data, and determine its eigenvalues and eigenvectors.

```
S <- cov(trackrcs[, -1])
R <- cor(trackrcs[, -1]); kable(R, digits = 3)
```

	x100m	x200m	x400m	x800m	x1500m	x3000m	marathon
x100m	1.000	0.941	0.871	0.809	0.782	0.728	0.669
x200m	0.941	1.000	0.909	0.820	0.801	0.732	0.680
x400m	0.871	0.909	1.000	0.806	0.720	0.674	0.677
x800m	0.809	0.820	0.806	1.000	0.905	0.867	0.854
x1500m	0.782	0.801	0.720	0.905	1.000	0.973	0.791
x3000m	0.728	0.732	0.674	0.867	0.973	1.000	0.799
marathon	0.669	0.680	0.677	0.854	0.791	0.799	1.000

```
eigen(R)$values
```

```
## [1] 5.80762446 0.62869342 0.27933457 0.12455472 0.09097174 0.05451882
## [7] 0.01430226
```

```
kable(eigen(R)$vectors, digits = 3)
```

-0.378	-0.407	-0.141	0.587	-0.167	0.540	0.089
-0.383	-0.414	-0.101	0.194	0.094	-0.745	-0.266
-0.368	-0.459	0.237	-0.645	0.327	0.240	0.127
-0.395	0.161	0.148	-0.295	-0.819	-0.017	-0.195
-0.389	0.309	-0.422	-0.067	0.026	-0.189	0.731

-0.376	0.423	-0.406	-0.080	0.352	0.240	-0.572
-0.355	0.389	0.741	0.321	0.247	-0.048	0.082

b) Determine the first two principal components for the standardized variables. Prepare a table showing the correlations of the standardized variables with the components, and the cumulative percentage of the total (standardized) sample variance explained by the two components.

the first two principal components for the standardized variables

```
res=prcomp((trackrcs)[,-1], scale. = FALSE)
# No scaling at this point because we are going to use the correlation matrix later

# Each PC is a linear combination of the original variables
#### res$rotation
kable(res$rotation[,1:2], digits = 3)
```

	PC1	PC2
x100m	-0.016	0.115
x200m	-0.039	0.290
x400m	-0.108	0.938
x800m	-0.005	0.013
x1500m	-0.013	0.036
x3000m	-0.039	0.079
marathon	-0.992	-0.119

correlation of the standardized variables with the components

This is following the formula in the text book on page 433, “Result 8.3” and “Equation 8-8”

```
eigenvalues=res$sdev^2
CorWithPC <-
  t(res$rotation[,1:2])%*%sqrt(diag(eigenvalues))%*%solve(sqrt(diag(diag(S))))
colnames(CorWithPC) <- colnames(trackrcs[, -1])
kable(t(CorWithPC), digits = 3)
```

	PC1	PC2
x100m	-0.678	4.827
x200m	-0.083	0.626
x400m	-0.021	0.187
x800m	-0.018	0.052
x1500m	-0.006	0.016
x3000m	-0.002	0.005
marathon	-0.001	0.000

cummulative percentage of total standardized sample variance explained by the 2 components

```
CorWithPC %>% apply(MARGIN=1,FUN=abs) %>% t() %>%
  apply(MARGIN=1,FUN=function(a) 100*cumsum(a)/sum(a)) %>% kable(digits = 3)
```

	PC1	PC2
x100m	83.665	84.473
x200m	93.961	95.435
x400m	96.615	98.710
x800m	98.782	99.624
x1500m	99.510	99.911
x3000m	99.815	99.997
marathon	100.000	100.000

c) Interpret the two principal components obtained in Part b. (Note that the first component is essentially a normalized unit vector and might measure the athletic excellence of a given nation. The second component might measure the relative strength of a nation at various running distances.)

It seems the first principal component is a measure of how much less time the athletes of a particular nation take to complete a race relative to their other fellow competitors from other nations. We can notice that athletes generally concentrate a lot of efforts in running very fast so that they complete their races in the shortest times possible in the 100 metre races and the marathon.

Clearly, the second principal component tells us about the physical strength of an athlete in a given race. We see that for 100 meters, the values are very high because athletes are giving their all while for the marathon, the values are actually negative because the athletes are usually very tired and they try to minimize using a lot of energy as a tactic to run for the very long distance.

d) Rank the nations based on their score on the first principal component. Does this ranking correspond with your intuitive notion of athletic excellence for the various countries?

```
NewScore <- as.matrix(trackrcs[, -1]) %*% as.matrix(res$rotation[, 1])
NewScore = cbind.data.frame(countries = trackrcs[, 1], NewScore = NewScore)
NewScore[, 1][order(NewScore[, 2], decreasing = TRUE)]

## [1] GBR KEN CHN JPN USA GER RUS NOR IRL ROM BEL AUS POR NED
## [15] ITA MEX POL CZE SUI KOR ESP KORS NZL BRA FIN FRA CAN HUN
## [29] DEN LUX SWE ARG TUR CHI GRE AUT INA SIN COL ISR IND MYA
## [43] TPE THA CRC PHI DOM MRI MAS GUA BER SAM COK PNG
## 54 Levels: ARG AUS AUT BEL BER BRA CAN CHI CHN COK COL CRC CZE DEN ... USA
```

This ranking indeed corresponds with my intuitive notion of the athletic excellence for the various countries. The principal components are indeed capturing well the ranking of the countries.

Question 2: Factor analysis

Perform a factor analysis of the national track records for women given in Table 1.9. Use the sample covariance matrix S and interpret the factors. Compute factor scores, and check for outliers in the data. Repeat the analysis with the sample correlation matrix R . Does it make a difference if R , rather than S , is factored? Explain.

Try both PC and ML as estimation methods. Notice that R's `factanal()` only does ML estimation. For the PC method you can use the `principal()` function of the `psych` package. What does it mean that the parameter rotation of `factanal()` is set to “varimax” by default (equivalently rotate of `principal()`)? Do not forget to check the adequacy of your model.

Tip: Read section “A Large Sample Test for the Number of Common Factors”.

```
factanal(trackrcs[, -1], factors = 3, covmat = S) # varimax is the default
```

```
##
## Call:
## factanal(x = trackrcs[, -1], factors = 3, covmat = S)
